- 1 Shortest path problem (nonnegative lengths)
- 2 Shortest path problem with negative lengths
- 3 All-pairs shortest paths
- 4 Traveling Salesman Problem

Shortest path problem

Problem

- Input: Directed graph $G = (V, E)$, source $s \in V$, length $\ell_e \geq 0$ ($e \in E$)
- Goal: Compute shortest distance and path from s to each $t \in V \setminus \{s\}$

Example

Shortest path problem

Problem

- Input: Directed graph $G = (V, E)$, source $s \in V$, length $\ell_e \geq 0$ ($e \in E$)
- Goal: Compute shortest distance and path from s to each $t \in V \setminus \{s\}$

Example

Dijkstra algorithm

Approach

- Initialize $S \leftarrow \{s\}$, $\text{dist}(s) \leftarrow 0$
- Repeatedly choose unexplored node $v \notin S$ which minimizes

$$\min_{e=(u,v): u \in S} \text{dist}(u) + \ell_e,$$

set $\text{dist}(v)$ to be the above value, and $S \leftarrow S \cup \{v\}$

Behavior of Dijkstra algorithm

$s = 1$

Behavior of Dijkstra algorithm

$s = 1$

Behavior of Dijkstra algorithm

$s = 1$

Behavior of Dijkstra algorithm

$s = 1$

Behavior of Dijkstra algorithm

$s = 1$

Correctness of Dijkstra algorithm

Induction

- Base case $S = \{s\}$ is clear ($\text{dist}(s) = 0$)
- Inductive step: $\ell(\textcolor{red}{P}) \geq \text{dist}(x) + \ell(\textcolor{blue}{x}, y) \geq \text{dist}(u) + \ell(u, v)$

shortest s - v path

first edge in P that leaves S

Efficient implementation

Dijkstra algorithm

```
1  $\text{dist}(s) \leftarrow 0, \text{dist}(v) \leftarrow \infty \ (\forall v \neq s);$ 
2 Create an empty priority queue  $H$ ;
3 foreach  $v \in V$  do  $\text{insert}(H, v, \text{dist}(v));$ 
4 while  $H$  is not empty do
5    $u \leftarrow \text{deletemin}(H);$ 
6   foreach  $e = (u, v) \in E$  do
7     if  $\text{dist}(v) > \text{dist}(u) + \ell_{(u,v)}$  then
8        $\text{dist}(v) \leftarrow \text{dist}(u) + \ell_{(u,v)};$ 
9        $\text{decreasekey}(H, v, \text{dist}(v));$ 
10 Return  $\text{dist};$ 
```

- insert : n times
- deletemin : n times
- decreasekey : $O(m)$ times

The running time depends on implementation of priority queue

Implementation	insert	deletemin	decreasekey	Total time
array	$O(1)$	$O(n)$	$O(1)$	$O(n^2)$
binary heap	$O(\log n)$	$O(\log n)$	$O(\log n)$	$O(m \log n)$
d -ary heap	$O(d \log_d n)$	$O(d \log_d n)$	$O(\log_d n)$	$O((nd + m) \log_d n)$
Fibonacci heap	$O(1)$ (amortized)	$O(\log n)$	$O(1)$ (amortized)	$O(m + n \log n)$
	n times	n times	$O(m)$ times	

- dense graph ($m = \Omega(n^2)$) \rightarrow array implementation is the faster
- sparse graph ($m = O(n)$) \rightarrow Fibonacci heap implementation is the faster

Compute the shortest distance from s to t

Outline

- 1 Shortest path problem (nonnegative lengths)
- 2 Shortest path problem with negative lengths
- 3 All-pairs shortest paths
- 4 Traveling Salesman Problem

Shortest path problem

Problem

- Input: Directed graph $G = (V, E)$, source $s \in V$, length ℓ_e ($e \in E$)
- Goal: Compute shortest distance and path from s to each $t \in V \setminus \{s\}$

Example

Shortest path problem

Problem

- Input: Directed graph $G = (V, E)$, source $s \in V$, length ℓ_e ($e \in E$)
- Goal: Compute shortest distance and path from s to each $t \in V \setminus \{s\}$

Example

Dijkstra algorithm may fail

if there exists a negative cycle, then there may not exist a shortest path

No negative cycle case

Observation

If no negative cycles exists, there is a shortest $s-t$ path that is simple

- Let P be the shortest $s-t$ path that uses the fewest edges
- If P contains a directed cycle (whose length is nonnegative), it can be removed without increasing the length of P

→ there exists a shortest $s-t$ path that has at most $n - 1$ edges

Dynamic programming (Bellman–Ford algorithm)

$\text{OPT}(i, v)$: length of shortest s – v path that uses at most i edges

Recursive formula

$$\text{OPT}(i, v) = \begin{cases} 0 & \text{if } i = 0 \text{ and } v = s \\ \infty & \text{if } i = 0 \text{ and } v \neq s \\ \min \left\{ \begin{array}{l} \text{OPT}(i-1, v) \\ \min_{(u,v) \in E} \text{OPT}(i-1, u) + \ell_{(u,v)} \end{array} \right\} & \text{if } i > 0 \end{cases}$$

Bellman–Ford

```
1 dist(s) ← 0, dist(v) ← ∞ (∀v ≠ s);
2 for i ← 1, 2, ..., n − 1 do
3   foreach e = (u, v) ∈ E do
4     └ dist(v) ← min{dist(v), dist(u) + ℓ(u,v)};
```

$O(mn)$ subproblems, each one takes $O(1)$ time \rightarrow $O(mn)$ time

Detecting a negative cycle

Proposition

$\exists s-t$ path that contains a negative cycle $\Rightarrow \lim_{i \rightarrow \infty} \text{OPT}(i, t) = -\infty$

Proposition

$\nexists s-t$ path that contains a negative cycle for any $t \in V$

$\iff \text{OPT}(n, v) = \text{OPT}(n-1, v)$ for any $v \in V$

- (\Rightarrow) because \exists shortest $s-v$ path that has at most $n-1$ edges
- (\Leftarrow) because $\text{OPT}(n, v) = \text{OPT}(n-1, v)$ ($\forall v \in V$) implies $\lim_{i \rightarrow \infty} \text{OPT}(i, v) = \text{OPT}(n-1, v) > -\infty$

➡ a negative cycle can be found in $O(mn)$ time

Outline

- 1 Shortest path problem (nonnegative lengths)
- 2 Shortest path problem with negative lengths
- 3 All-pairs shortest paths**
- 4 Traveling Salesman Problem

All-pairs shortest paths problem

Problem

- Input: Directed graph $G = (V, E)$ and length ℓ_e ($e \in E$)
- Goal: Compute shortest distance for every pair $(s, t) \in V^2$

applicable only when $\ell_e \geq 0$ ($\forall e \in E$)

- Running **Dijkstra alg.** for every $s \in V \rightarrow O(mn + n^2 \log n)$ time
- Running Bellman–Ford alg. for every $s \in V \rightarrow O(mn^2)$ time
- Better alternative: Floyd–Warshall alg. $\rightarrow O(n^3)$ time

Dynamic programming (Floyd–Warshall algorithm)

- $V = \{1, 2, \dots, n\}$
- $\text{OPT}(i, j, k)$: shortest i – j dist. only using vertices in $\{1, 2, \dots, k\}$

Recursive formula

$$\text{OPT}(i, j, k) = \begin{cases} \min \left\{ \begin{array}{l} \text{OPT}(i, j, k-1) \\ \text{OPT}(i, k, k-1) + \text{OPT}(k, j, k-1) \end{array} \right\} & \text{if } k > 0 \\ 0 & \text{if } k = 0 \text{ and } i = j \\ \ell_{(i,j)} & \text{if } k = 0 \text{ and } (i, j) \in E \\ \infty & \text{otherwise} \end{cases}$$

$O(n^3)$ subproblems, each one takes $O(1)$ time \rightarrow $O(n^3)$ time

Implementation of Floyd–Warshall algorithm

Floyd–Warshall algorithm

```
1 for  $i \leftarrow 1, 2, \dots, n$  do
2   for  $i \leftarrow 1, 2, \dots, n$  do
3     if  $i = j$  then  $\text{dist}(i, j) \leftarrow 0$ ;
4     else if  $(i, j) \in E$  then  $\text{dist}(i, j) \leftarrow \ell_{(i, j)}$ ;
5     else  $\text{dist}(i, j) \leftarrow \infty$ ;
6 for  $k \leftarrow 1, 2, \dots, n$  do
7   for  $i \leftarrow 1, 2, \dots, n$  do
8     for  $j \leftarrow 1, 2, \dots, n$  do
9        $\text{dist}(i, j) \leftarrow \min\{\text{dist}(i, j), \text{dist}(i, k) + \text{dist}(k, j)\}$ ;
```

Detecting a negative cycle

Proposition

\exists negative cycle including $i \in V \Rightarrow \text{OPT}(i, i, n) < 0$

→ a negative cycle can be found in $O(n^3)$ time

Another approach: reweighting edges

Dijkstra algorithm is applicable by reweighting edges

- reweight the edges by potential $\pi: V \rightarrow \mathbb{R}$

$$\ell'_{(u,v)} := \ell_{(u,v)} + \pi(u) - \pi(v) \ (\geq 0)$$

- compute reweighted shortest distances

$$\sum_{i=1}^k \ell'_{(v_i, v_{i+1})} = \sum_{i=1}^k \ell_{(v_i, v_{i+1})} + \underbrace{\pi(v_1) - \pi(v_{k+1})}_{\text{constant}}$$

Johnson's algorithm

- 1 add a new node s and add a new edge (s, v) with $\ell_{(s,v)} = 0$ ($\forall v \in V$);
- 2 compute $\text{dist}(s, v)$ for all $v \in V$ by Bellman–Ford alg.;
- 3 reweight the edges as $\ell'_{(u,v)} := \ell_{(u,v)} + \text{dist}(s, u) - \text{dist}(s, v)$;
- 4 compute reweighted shortest distances $\text{dist}'(u, v)$ by Dijkstra alg.;
- 5 compute original shortest distances
 $\text{dist}(u, v) = \text{dist}'(u, v) - \text{dist}(s, u) + \text{dist}(s, v)$;

→ $O(mn + n^2 \log n)$ time

Outline

- 1 Shortest path problem (nonnegative lengths)
- 2 Shortest path problem with negative lengths
- 3 All-pairs shortest paths
- 4 Traveling Salesman Problem

Traveling Salesman Problem

Problem

- Input: set of vertices V with distance $d: \binom{V}{2} \rightarrow \mathbb{R}_+$
- Goal: find a shortest cycle that visits all vertices exactly once

naive algorithm: $\Theta(n!)$ time ($(n-1)!$ possibilities)

→ improve it to $O(n^2 2^n)$

Example

Traveling Salesman Problem

Problem

- Input: set of vertices V with distance $d: \binom{V}{2} \rightarrow \mathbb{R}_+$
- Goal: find a shortest cycle that visits all vertices exactly once

naive algorithm: $\Theta(n!)$ time ($(n-1)!$ possibilities)

→ improve it to $O(n^2 2^n)$

Example

length = 11

Dynamic programming (Held–Karp algorithm)

- $V = \{1, 2, \dots, n\}$
- $\text{OPT}(S, j)$: length of the shortest 1- j path through every vertices in S
 $S \subseteq V \setminus \{1\}, j \in V \setminus S$. optimal value of the original problem is $\text{OPT}(V \setminus \{1\}, 1)$

Recursive formula

$$\text{OPT}(S, j) = \begin{cases} \min_{i \in S \setminus \{j\}} \text{OPT}(S \setminus \{i\}, i) + d(i, j) & \text{if } |S| > 0 \\ d(1, j) & \text{if } |S| = 0 \end{cases}$$

$O(n2^n)$ subproblems, each one takes $O(n)$ time $\rightarrow O(n^2 2^n)$ time
